

Flowers can grow at high elevations if growers match them to cold, exposed sites and make the most of a short season. Success depends on careful timing, free draining soil and thoughtful shelter, with young plants often started in a protected place.

Making the most of a brief season

Snow may remain on the ground well into spring, and frost can arrive again before autumn ends. That leaves little time for plants to grow and bloom. Rather than follow fixed dates, growers watch local conditions, including when soil has thawed and when seedlings are safe to plant outdoors.

Seeds and cuttings can be started in a greenhouse or another sheltered spot while garden soil is still cold. Before moving these young plants outside, growers introduce them gradually to wind, sun and lower temperatures. This adjustment period is called hardening off.

Summer weather in the mountains can shift without warning. Tender plants may need protection during a sudden cold spell. Covers should then be taken off or aired as the weather warms, so plants do not overheat.

Selecting plants for mountain conditions

Flowers from mountain habitats, along with species suited to similar climates, are often sensible choices. Many alpine plants stay low to the ground, gaining some protection from strong winds. Their compact growth can also help them cope with cold and snow.

Each species has its own preferences. Some need full sun and soil that drains quickly. Others do better in a cool spot with partial shade. Cold alone does not make a site suitable: a flower that grows well on a rocky slope may

fail in a bed that stays wet.

Plant and seed sources deserve care too. Wild populations need protection, so choose cultivated plants or seeds instead of taking flowers from mountain habitats.

Getting the ground and care right

Soil in mountain areas may be thin, stony and fast draining, but conditions differ between sites. Check the ground before planting. Raised beds or added grit can improve drainage where needed. For plants that dislike wet roots, standing water can cause serious harm, especially in cold weather.

Fast drainage does not remove the need to water. Newly planted flowers need attention as their roots settle in. Base watering on the soil and the weather. Sun and wind can dry exposed ground quickly, so check conditions rather than assuming plants will stay moist.

Wind protection can help, but consider its effects before adding a wall or screen. It may block useful light or cause snow to collect. A small change in position can make one part of a garden suitable and another difficult. Watching how each spot behaves helps guide planting and care.

Common questions about alpine flowers

Is a greenhouse necessary for alpine flowers?

No. A greenhouse is useful for raising plants and shielding them while young, but many hardy alpine species can grow outside if the site meets their needs.

Will mountain flowers grow in a lowland garden?

Some will, if they receive suitable light and drainage and do not face unsuitable temperatures. Other kinds may suffer through long periods of heat or damp winter soil.

Is it all right to pick flowers in the wild?

Choose cultivated plants or seeds instead. Taking wild flowers can damage local populations, and collecting them may be restricted.
